Abstract of FR2763880

The novel continuous process makes special coverings for floors or walls. A layer (2) of polymer binder mixed with elastomeric particles or granules is deposited on a base material carrying it along. The layer is continuously compressed and hardened, passing it through an oven (13). Novel features include the substrate, which is permeable to steam injected through it and the layer as they pass over, prior to or during compression of the elastomeric layer. Also claimed are: a plant to carry out the process; a synthetic grass covering, including blades of synthetic grass; a flexible underlayer for sports areas; and a band of covering material for walls or floors. This has improved sound deadening properties and is made with woven or non-woven fabric layers.
